Abstract

Isopropanol represents a widely-used commercial alcohol which is currently produced from petroleum. In nature, isopropanol is excreted by some strains of Clostridium beijerinckii, simultaneously with butanol and ethanol during the isopropanol butanol ethanol (IBE) fermentation. In order to increase isopropanol production, the gene encoding the secondary-alcohol dehydrogenase enzyme from C. beijerinckii NRRL B593 (adh) which catalyzes the reduction of acetone to isopropanol, was cloned into the acetone, butanol and ethanol (ABE)-producing strain C. acetobutylicum ATCC 824. The transformants showed high capacity for conversion of acetone into isopropanol (> 95%). To increase isopropanol production levels in ATCC 824, polycistronic transcription units containing, in addition to the adh gene, homologous genes of the acetoacetate decarboxylase (adc), and/or the acetoacetyl-CoA:acetate/butyrate:CoA transferase subunits A and B (ctfA and ctfB) were constructed and introduced into the wild-type strain. Combined overexpression of the ctfA and ctfB genes resulted in enhanced solvent production. In non-pH-controlled batch cultures, the total solvents excreted by the transformant overexpressing the adh, ctfA, ctfB and adc genes were 24.4 g/L IBE (including 8.8 g/L isopropanol), while the control strain harbouring an empty plasmid produced only 20.2 g/L ABE (including 7.6 g/L acetone). The overexpression of the adc gene had limited effect on IBE production. Interestingly, all transformants with the adh gene converted acetoin (a minor fermentation product) into 2,3-butanediol, highlighting the wide metabolic versatility of solvent-producing Clostridia.

Keywords: Clostridium, Butanol, Biobutanol, Isopropanol, IBE fermentation, 2,3-butanediol, Acyl-CoA transferase

Introduction

The limited supply and the negative environmental effects of the use of petroleum-derived fuels and chemicals have stimulated efforts for the development of more environmentally-friendly processes. In this respect, the fermentation of carbohydrates into acetone, butanol and ethanol (ABE) or isopropanol, butanol and ethanol (IBE) is a promising way for the production of green chemicals and fuels. In the past, both ABE and IBE fermentations were performed worldwide at industrial scale until they were replaced by petrochemical processes (Jones and Woods 1986; Rogers et al. 2006). Many resources are currently being devoted to develop economically-viable fermentation processes based primarily on lignocellulosic biomass hydrolysates as substrates (Dürre 2007, 2008; López-Contreras et al. 2010; Green 2011).

For fuel applications, the IBE mixture appears to be more attractive than the ABE one. Isopropanol shows a higher energy density than acetone (23.9 MJ/L vs 22.6 MJ/L) and this mixture has already been used as an additive for gasoline or diesel oil (Peralta-Yahya and Keasling 2010). Isopropanol can be catalytically condensed into di-isopropyl ether (DIPE) (Logsdon and Loke 2000). DIPE displays good fuel properties and could substitute methyl tert-butyl ether (MTBE) as isoctane index enhancer in gasoline composition (Huang and Sorensen 1990). Another important potential application of biologically-produced isopropanol is as a precursor for green propylene, which is the second most important chemical intermediate in the petrochemical industry after ethylene.
Propylene is used in many chemical reactions for the synthesis of a wide variety of products, including plastic materials.

The clostridial species that produce neutral solvents (ABE or IBE) are strictly anaerobes, rod-shaped and spore-forming bacteria. Most of them, such as *C. acetobutylicum* ATCC 824, produce ABE but some others, such as *C. beijerinckii* NRRL B593, excrete IBE (George et al. 1983; Chen and Hiu 1986). ABE and IBE batch fermentations are similar, displaying a biphasic kinetic pattern (Jones and Woods 1986; Girbal and Soucaille 1998). After production of acetic and butyric acids in exponential growth, fermentation switches to formation of neutral solvents shortly before entering stationary phase. In the IBE fermentation, depending on the strain and the cultivation conditions, residual acetone may also be an end-product (Ismaiel et al. 1993).

In *C. beijerinckii* NRRL B593, the reduction of acetone into isopropanol is catalyzed by a NADPH-dependent secondary-alcohol dehydrogenase (s-Adh), which has been extensively characterized (Yan et al. 1988; Ismaiel et al. 1993; Korkhin et al. 1998; Goihberg et al. 2010). Although the s-Adh was clearly distinct from clostridial primary-alcohol dehydrogenases (Chen 1995) that reduce butyraldehyde into butanol, the s-Adh showed activity on both primary and secondary alcohols, with a preference for secondary ones (Ismaiel et al. 1993). Kinetic studies confirmed that the physiological substrate was acetone.

Metabolic engineering has been used to create pathways for isopropanol production in *Escherichia coli*. Introduction of four genes from *C. acetobutylicum* (ctfA, ctfB, adc and thiolase (thl)) into *E. coli* generated a strain capable of producing acetone (Bermejo et al. 1998). By introduction of the *C. beijerinckii* adh gene in combination with the aforementioned genes, isopropanol excretion by *E. coli* was achieved up to the concentrations of 4.9 g/L (Hanaï et al. 2007) and 13 g/L (Jojima et al. 2008). The engineered *E. coli* strains surpassed the best reported wild-type clostridial strains, *C. beijerinckii* and *C. isopropyllicum*, excreting approximately 4 g/L isopropanol (Groot and Luyben 1983; Chen and Hiu 1986; Matsumura et al. 1992). A major advantage of the engineered *E. coli* strains was the lack of important competing pathways for by-products. Recently, the adh gene from *C. beijerinckii* was cloned into the ABE-producing strain *C. acetobutylicum* ATCC 824. The resulting transformants excreted 6.1 g/L isopropanol and a minor amount of acetone (Lee et al. 2012).

In the present study, different IBE-producing transformants of *C. acetobutylicum* that showed high isopropanol excretion capacities have been constructed. The fermentation performances of the transformants were characterized in batch cultures using laboratory-scale bioreactors with or without pH-control and compared to those of the wild-type IBE or ABE-producing strains. In addition, formation of 2,3-butanediol by *C. acetobutylicum* transformant strains harbouring the adh gene was described and characterized for the first time.

### Materials and methods

#### Strains and cultivation conditions

The microorganisms used are listed in Table 1. *E. coli* culture stocks were stored at −80°C in 20% (v/v) glycerol. *E. coli* strains were cultivated at 37°C with agitation (250 rpm) in LB (lysogeny broth) medium (Bertani 2004). For cultivation of *E. coli* BW25113 harbouring pMTL500E based plasmids, the LB medium was supplemented with 2% (w/w) glucose.

Clostridial wild-type and transformants were stored as spore suspensions at −20°C in 15% (v/v) glycerol. Prior to the inoculation of pre-cultures, each spore suspension (500 µL) was heat-shocked in a water bath for 10 min at 70°C (*C. acetobutylicum* ATCC 824 and its transformants) or 1 min at 100°C (*C. beijerinckii* NRRL B593). Culture media for *Clostridia* were made anaerobic by sparging with nitrogen gas. Cultures and pre-cultures were performed in CM1 medium (Kuit et al. 2012) which contains, per liter: yeast extract, 5.0 g; KH$_2$PO$_4$, 1.0 g; K$_2$HPO$_4$, 0.76 g; ammonium acetate, 3.0 g; *p*-aminobenzoic acid, 0.10 g; MgSO$_4$, 7 H$_2$O, 1.0 g; and FeSO$_4$, 7 H$_2$O, 0.5 g; glucose, 90 g. Pre-cultures of

C. beijerinckii were grown in medium containing 60 g/L glucose.

Batch fermentations were carried out anaerobically in 2-L (1-L working volume) Applikon glass bioreactors (Applikon, The Netherlands) using CM1 medium. When needed, pH was maintained at 5.0 by automatic addition of 4 M KOH solution. Static flask fermentations were carried out anaerobically in 120 mL serum bottles with 50 mL of CM1 medium.

For the preparation of clostridial competent cells, cells were grown on CG medium (Roos et al. 1985), as described previously (Oultram et al. 1988). When required, culture media were supplemented with ampicillin (100 μg/mL), chloramphenicol (30 μg/mL), erythromycin (50 μg/mL) or 30 μg/mL for liquid cultures and plates, respectively.

Microbial growth was monitored by optical density measurements at 600 nm (Pharmacia Biotech Ultrospec 2000).

Plasmid construction and transformation

Genomic DNA from Clostridium strains was isolated using GenElute bacterial genomic DNA kit from Sigma-Aldrich. Plasmid DNA from E. coli strains was extracted using the GeneJet plasmid miniprep kit from Fermentas. PCR amplifications were done using high fidelity PCR buffer (pH 8.5) containing DTT (0.2 mM) and a set of primers (Table 2) in 100 μL of reaction mixture (Roche). DNA restrictions and ligations were performed using New England Biolabs restriction master mix (Roche). DNA restrictions and ligations were performed using T4 DNA-Ligase enzyme, respectively. The oligonucleotides were based on the restriction enzymes (ApaI, Fnu4HI, SpeI, SphI, XbaI and Xhol) and T4 DNA-Ligase enzyme, respectively. The oligonucleotides used are listed in Table 2 and were synthesized by Eurogenetec. Chemically competent E. coli strains were prepared using the Z-competent kit from Zymo-research. Kits were used according to supplier protocols.

The constructs used for the C. acetobutylicum transformation were based on the E. coli/Clostridium shuttle vector pMTL500E (Table 1). The thiolase promoter was PCR-amplified from genomic-DNA of C. acetobutylicum ATCC 824 using thlp_for and thlp_rev oligonucleotides and digested by Apal and SphI. The adc gene was PCR-amplified from C. beijerinckii NRRL B593 genomic-DNA using adh_for and adh_rev oligonucleotides and digested by Apal and Xhol. The thl promoter and adh gene sequences were simultaneously cloned into pMTL500E plasmid (digested by SphI and Xhol) to yield pFC002 construct. Genes from C. acetobutylicum ATCC 824 were amplified by PCR on genomic DNA using adf_for and adf_rev oligonucleotides for adc, ctfAB_for and ctfAB_rev oligonucleotides for ctfA and ctfB. PCR amplifications of adc gene and ctfA_olfB genes were digested by Xhol and Sphl restriction enzymes and cloned into pFC002 digested Xhol and XbaI to yield pFC005 and pFC006, respectively. PCR amplification of adc gene was subsequently cloned into pFC006 digested Xhol and XbaI to yield pFC007.

Plasmid DNA constructs were introduced into chemically competent E. coli DH10B harbouring pAN2 (Heap et al. 2007) for methylation prior to transformation into C. acetobutylicum as described earlier (Mermelstein and Papoutsakis 1993). Correct methylation was checked by restriction analysis with Fnu4HI. Methylated pFC002, pFC005, pFC006, pFC007 and methylated pMTL500E plasmids (Table 1) were electroporated into C. acetobutylicum ATCC 824 as described by Oultram et al (Oultram et al. 1988). Erythromycin-resistant colonies were cultivated in CGM liquid medium and total DNA was extracted as described above. The presence of the respective construct in the transformants obtained was confirmed by PCR on DNA extracted from the different colonies using specific oligonucleotides for the specific inserts. Transformant strains harboured the right construct were found for all constructs (results not shown). Transformant strains were stored as spore suspensions and kept at −20°C.

The thiolase transcription unit was amplified from C. acetobutylicum genomic DNA using oligonucleotides thlp_for and thlp_rev (Table 2). The amplify was cloned into pCR blunt II Topo (Invitrogen) to yield pTHL. The plasmid pTHL was cotransformed with pTHL. The plasmid pTHL was cotransformed with pMTL500E in chimiocompetent E. coli BW25113.

Reduction of ketones by cell-free extracts

For preparation of cell-free extracts (CFEs) for enzymatic assays, C. acetobutylicum transformants and C. beijerinckii wild type strains were grown anaerobically in 100 mL of CM1 medium with 60 g/L glucose. After 15–20 h of culture, cells were harvested at 4°C by centrifugation at 15,000 g for 7 min (OD600: 1.5-2.0). Pellets were suspended in 20 mL of 50 mM sodium-HEPES buffer (pH 8.5) containing DTT (0.2 mM) and a set of

protease inhibitors (Complete; Mini, Roche, 1 table in 50 mL) and washed twice. Pellets were then suspended in 3 mL of 50 mM sodium-HEPES buffer. Cell suspensions were frozen in liquid nitrogen and stored overnight at ~80°C in anaerobic conditions. Cell suspensions were then slowly thawed, loaded in a French Press (Thermo Electron Corporation) and homogenized by two passes at 16,000 psi. When used, CFEs were kept on ice. Protein content in the CFEs was determined by the Bradford method (Biorad) with BSA as standard.

Reduction of acetone or racemic acetoin (D/L 3-hydroxy-2-butanone, Fluka) by s-Adh was carried out at 37°C in 50 mM of Tris buffer (pH 7.5) with 0.2 mM of NADPH and 50 mM of substrate. NADPH decrease was monitored by absorbance decrease at 340 nm using a Safire spectrophotometer (Tecan).

**Analytical procedures**

Samples taken during fermentation were centrifuged at 20,000 g for 5 min and supernatants were stored at ~20°C. Metabolite concentrations (sugars, organic acids, solvents and 2,3-butanediol) were determined by HPLC as previously described (Gosselink et al. 1995; Siemerink et al. 2011). A solution of 4-methyl valeric acid (Sigma-Aldrich) at 30 mM was used as an internal standard.

**Results**

**Construction of expression vectors**

The well-studied ABE-producing strain *C. acetobutylicum* ATCC 824 was engineered to be an IBE producer. For this purpose, the coding sequence of the *adh* gene from *C. beijerinckii* NRRL B593 was cloned downstream of the promoter sequence of the thiolase gene (*thl*) from *C. acetobutylicum* ATCC 824 to form pFC002 plasmid (Table 1). The promoter sequence of the thiolase gene was chosen in order to maximize expression of the *adh* gene, since the thiolase gene of *C. acetobutylicum* was reported to be constitutively expressed (Hartmanis and Gatenbeck 1984; Tummalra et al. 1999; Alsaker and Papoutsakis 2005). To up-regulate the acetone pathway in the host organism, genes encoding the enzymes active in acetoacetate:CoA to acetoconversion i.e. acetoacetate decarboxylase (*adc*) and acetocetyl-CoA : acetate/butyrate:CoA transferase subunits A and B (*ctfA* and *ctfB*) were cloned into pFC002, downstream of the *adh* gene, resulting in the construct pFC007 (Table 1). Genes *adc*, *ctfA* and *ctfB* were expressed under the control of the *thl*-promoter. The role of each gene over expressed in pFC007 was subsequently assessed by constructing different combinations of *adh*, *adc*, *ctfA* and *ctfB* genes. The plasmid pFC005 contained *adh* and *adc* genes and pFC006 contained *adh*, *ctfA* and *ctfB* genes (Table 1).

**Expression of isopropanol pathway genes in *E. coli***

To assess their ability to promote isopropanol production, the constructs pFC002, pFC005, pFC006, pFC007 and pMTL500E were co-transformed with pTHL plasmid into *E. coli* BW25113. The pTHL plasmid contained the thiolase gene (*thl*) from *C. acetobutylicum* ATCC 824 (Stim-Herndon et al. 1995) to allow sufficient formation of acetoactyl-CoA by *E. coli*. Productions of solvents by *E. coli* transformants are shown in Figure 1. All transformants produced ethanol, but only the transformants which, in addition to thiolase and *adh* genes, expressed *ctfA* and *ctfB* genes, i.e. transformants harbouring pFC006 (*thlp[adh; ctfA; ctfB]*) or pFC007 (*thlp[adh; adc; ctfA; ctfB]*) plasmids, produced isopropanol (3–8 mM). The *E. coli* transformants harbouring pTHL and pFC005 (*thlp[adh; adc]*) plasmids or harbouring pTHL and pMTL500E (control) plasmids did not produce isopropanol.

**Effect of expression of the *adh* gene on the product pool of *C. acetobutylicum***

Plasmids pMTL500E, pFC002, pFC005, pFC006 and pFC007 were independently electroporated into *C. acetobutylicum*. The fermentation performance of the different *C. acetobutylicum* transformant strains was studied and compared with those of the wild-type strains (WT) in batch cultures performed in bioreactors with a 1 L-working volume. Cultures were performed with or without pH regulation. When pH regulated, the system was setup in such a way that once the pH had dropped to 5.0 it was kept at that level by the addition of KOH. Table 3 shows final fermentation performances of *C. acetobutylicum* transformants with pH regulation at 5.0.

Expression of *adh* by strains ATCC 824(pFC002), ATCC 824(pFC005), ATCC 824(pFC006) and ATCC 824(pFC007) resulted in the reduction to isopropanol of about 95% of the acetone natively produced. In contrast to ATCC 824 WT or ATCC 824(pMTL500E) that produced between 0.5 and 1.1 g/L acetoin (3-hydroxy-2-
butanone) (Jones and Woods 1986; Xiao and Xu 2007), very low concentrations of acetoin were detected in cultures of transformants expressing the \textit{adh} gene. However, D and/or L 2,3-butanediol (2,3-BD) accumulated at 0.5-0.6 g/L when the pH was regulated at 5.0 and at 0.6-1.2 g/L when the pH was not regulated. No meso-2,3-BD was identified. Production of 2,3-BD was concomitant with production of IBE. It is worth noting that 2,3-BD was not detected in cultures of \textit{C. beijerinckii} NRRL B593, probably because the organism does not produce acetoin. The enzymatic reduction of acetone and acetoin by cell-free extracts of ATCC 824(pMTL500E), ATCC 824(pFC002), ATCC 824(pFC005) and NRRL B593 WT was tested \textit{in vitro} (Table 4). The cell-free extracts of ATCC 824(pFC002), ATCC 824(pFC007) and NRRL B593 WT displayed significantly higher reduction activities towards acetone and acetoin than those of ATCC 824(pMTL500E) used as control (Table 4).

Early isopropanol production in static flask culture
As the constitutive promoter of the \textit{thl} gene was used to control gene expression (Tummala et al. 1999), the isopropanol production by ATCC 824(pFC007) was expected to start concomitantly with the production of butyric acid. Product excretion in the first hours of fermentation was studied in static flask fermentations. Butyric acid was detected prior to any solvent in all cultures of ATCC 824 transformants. The transformants expressing \textit{ctfA} and \textit{ctfB} genes \textit{i.e.} harbouring pFC006 and pFC007 excreted isopropanol earlier than the wild type strain or other transformants (data not shown) and prior to any other solvent.

### Early isopropanol production in static flask culture

As the constitutive promoter of the \textit{thl} gene was used to control gene expression (Tummala et al. 1999), the isopropanol production by ATCC 824(pFC007) was expected to start concomitantly with the production of butyric acid. Product excretion in the first hours of fermentation was studied in static flask fermentations. Butyric acid was detected prior to any solvent in all cultures of ATCC 824 transformants. The transformants expressing \textit{ctfA} and \textit{ctfB} genes \textit{i.e.} harbouring pFC006 and pFC007 excreted isopropanol earlier than the wild type strain or other transformants (data not shown) and prior to any other solvent.

### Kinetics of IBE production by \textit{C. acetobutylicum} transformants

The fermentation kinetics of ATCC 824 transformants were first investigated using a pH set-point of 5.0. The

[Table 3](#) Performance of \textit{C. acetobutylicum} ATCC 824 and its transformants in 45-h cultures performed with pH regulation at 5.0

1. Early isopropanol production in static flask culture

As the constitutive promoter of the \textit{thl} gene was used to control gene expression (Tummala et al. 1999), the isopropanol production by ATCC 824(pFC007) was expected to start concomitantly with the production of butyric acid. Product excretion in the first hours of fermentation was studied in static flask fermentations. Butyric acid was detected prior to any solvent in all cultures of ATCC 824 transformants. The transformants expressing \textit{ctfA} and \textit{ctfB} genes \textit{i.e.} harbouring pFC006 and pFC007 excreted isopropanol earlier than the wild type strain or other transformants (data not shown) and prior to any other solvent.

2. Kinetics of IBE production by \textit{C. acetobutylicum} transformants

The fermentation kinetics of ATCC 824 transformants were first investigated using a pH set-point of 5.0. The
fermentation profile and performances of the control strain ATCC 824(pMTL500E) were similar to those of *C. acetobutylicum* ATCC 824 WT in the first 45 h of fermentation (Table 3). The expression of only the *adh* gene in ATCC 824(pFC002) resulted in lower solvent production (15.1 g/L IBE of which 4.8 g/L isopropanol) than ATCC 824(pMTL500E) without the *adh* gene. Moreover, the productivity of ATCC 824(pFC002) at 30 h was 25% lower than that of ATCC 824(pMTL500E). In comparison to ATCC 824(pFC002), the wild-type IBE-producer *C. beijerinckii* NRRL B593 excreted less IBE (13.2 g/L of which 4.5 g/L isopropanol), but reassimilated more efficiently the acids previously excreted. Thus NRRL B593 displayed higher solvent yield (0.36 gIBE/gglc for NRRL B593 vs 0.29-0.30 gIBE/gglc for ATCC 824(pFC002)).

ATCC 824(pFC007) surpassed ATCC 824(pFC002) in the production of IBE, indicating that the overall metabolic activity was stimulated by the expression of pFC007 genes. ATCC 824(pFC007) produced more solvents (20.4 g/L IBE of which 7.3 g/L) and less acids than ATCC 824(pFC002) (15.1 g/L IBE of which 4.8 g/L isopropanol). In addition, the fermentation period was shorter and stopped about 10–15 hours earlier than for ATCC 824(pFC002) (Figure 2). Consequently, the solvent productivity after 30 h by ATCC 824(pFC007) (0.67 g/L h) was 2.6 times higher than that of ATCC 824(pFC002).

Cultures of ATCC 824(pFC005) and ATCC 824 (pFC006) were performed to evaluate the contribution of each gene to the improvement of the ATCC 824(pFC007) phenotype (Table 3). Both strains produced more IBE than ATCC 824(pFC002). The combined overexpression of the *ctfA* and *ctfB* genes along with expression of *adh* conferred to ATCC 824(pFC006) a fermentation profile similar to that of ATCC 824(pFC007) (Table 3). The final concentration of acids in the ATCC 824(pFC006) culture was slightly lower than that of ATCC 824(pFC002). As with ATCC 824(pFC007), fermentations with ATCC 824(pFC006) stopped 10–15 hours earlier than with the other transformants (Figure 2). The resulting solvent productivity after 30 h (0.62 g/L h) was 2.0 times higher than ATCC 824(pFC002). In ATCC 824(pFC005), the overexpression of *adc* along with expression of *adh* gene had a more pronounced effect on the production of isopropanol (+27%) than on the production of butanol (+7%) when compared with ATCC 824(pFC002). The fermentation performances of ATCC 824(pFC005) were lower than those of ATCC 824(pFC006) or ATCC 824(pFC007) and no shortening of the fermentation period was observed. Besides, ATCC 824(pFC005), ATCC 824 (pFC006) and ATCC 824(pFC007) exhibited the same solvent yield than ATCC 824(pFC002), ATCC 824(pMTL500E) and the WT.

**Effect of pH control**

In order to assess the effect of the culture mode, another set of fermentations was performed without pH control (Table 5). For every strain tested, the minimum pH value reached was 4.7-4.8 (data not shown). The glucose consumptions were roughly similar to those without pH regulation. A better reassimilation of acetic and butyric acids was observed leading to better solvent titres, yields and productivities. The excretion profiles of metabolites for each strain were similar to the corresponding ones with pH regulation at 5.0. The highest solvent productions were obtained with ATCC 824(pFC007) that produced 24.4 g/L IBE (of which 8.8 g/L was isopropanol) and ATCC 824(pFC006) that produced 24.0 g/L IBE (of which 8.0 g/L was isopropanol). Lack of sporulation and extensive cell lysis were observed in cultures of ATCC 824(pFC006) or ATCC 824(pFC007) performed without pH control, highlighting the strong inhibitory effect of solvents in the early phase of cellular growth.

**Discussion**

In the latest developments related to the ABE fermentation process, acetone was considered to be undesirable co-product, whereas butanol is the main product of interest. Over the past few decades, various strategies have been developed to decrease the production of acetone and increase the production of butanol (Nair et al. 1994; Nair and Papoutsakis 1994; Harris et al. 2000; Sillers et al. 2008; Jiang et al. 2009; Sillers et al. 2009; Han et al. 2011). The intracellular conversion of acetone into isopropanol was an attractive alternative to avoid acetone excretion and produce a valuable alcohol. The *C. beijerinckii* NRRL B593 strain reduced acetone naturally thanks to a secondary-alcohol dehydrogenase (s-Adh) but the final titers of solvents by the NRRL B593 (George et al. 1983; Survase et al. 2011) were lower than those of the best ABE producers (Monot et al. 1982; Qureshi and Blaschek 1999).

In this study, we have constructed four plasmids harbouring the *adh* gene from *C. beijerinckii* NRRL B593 and the genes from *C. acetobutylicum* ATCC 824 that are part of the metabolic pathway from acetoacetyl-CoA to acetone. The cloned genes were successfully expressed in both *E. coli* BW25113 and *C. acetobutylicum* ATCC 824. In *E. coli*, the expression of *ctfA* and *ctfB* along with *adh* and *thl* genes allowed for the production of isopropanol. The lack of the *adc* gene did not prevent the de-carboxylation of acetoacetate by *E. coli* harbouring pFC006, probably because of the instability of the molecule in acidic conditions (Hay and Bond 1967). The final concentration of isopropanol in cultures of *E. coli* strains
expressing ctfA and ctfB genes (pTHL and pFC006 or pTHL and pFC007) was lower than those previously reported by other groups (Hanai et al. 2007; Atsumi and Liao 2008; Jojima et al. 2008; Yoshino et al. 2008). In our study, E. coli cultures were not optimised, but carried out with the purpose of checking the validity of each construct.

The plasmids were electroporated in C. acetobutylicum ATCC 824. The expression of adh gene allowed transformants to reduce natively produced acetoin and acetone to 2,3-BD and isopropanol, respectively. Either the D or L forms of 2,3-BD or a combination of both but no meso-2,3-BD was produced. The achiral HPLC used in the present study did not differentiate between the D and L enantiomers. Since the activity of s-Adh on acetoin had never been described, this result extends the range of substrates known for this enzyme (Ismaiel et al. 1993). Recently, the production of 2,3-BD by C. acetobutylicum transformants expressing an acetoin reductase (acr) from C. beijerinckii NCIMB 8052 was reported (Siemerink et al. 2011). The resulting strains also produced 2,3-BD but did not produce isopropanol. For future applications, the

production of 2,3-BD by ATCC 824 transformants is still very far from that of Klebsiella pneumoniae (up to 150 g/L of 2,3-BD) (Ma et al. 2009).

Each transformant of ATCC 824 was characterised in a batch culture either with pH regulation at 5.0 or without pH regulation. All transformants of ATCC 824 and the wild type displayed higher solvent production levels when grown without pH-regulation. The solvent yield based on glucose consumption did not depend on the culture conditions (pH control or not). Acid assimilation was improved in the cultures without pH regulation, as also suggested by the increase of the C3 compound (acetone or isopropanol) productions. When the pH was not regulated, the pH value of the culture dropped below 5.0, increasing the concentrations of the protonated form of the acids. This has been associated with the onset of solventogenesis (Monot et al. 1984; Hüsemann and Papoutsakis 1988). Therefore, the high level of protonated acid forms in pH not-regulated cultures of ATCC 824 transformants might trigger solventogenesis at a lower concentration of total acids (protonated plus ionized) and drive more the carbon flux towards butanol or ethanol formation.

The expression of only the adh gene lowered total solvent production by ATCC 824(pFC002) compared to the wild type and the transformant harbouring the empty vector (pMTL500E). The lower solvent excretion by ATCC 824(pFC002) could be explained by the higher toxicity of isopropanol compared to acetone, as suggested by the octane/water partition coefficients (logKow) values i.e. 0.05 for isopropanol and −0.25 for acetone (Yaws and Sachin 1999). The logKow was reported to be a good estimation for solvent toxicity (Vermue et al. 1993; Heipieper et al. 1999). The logKow for isopropanol and acetone are 2.05 and 1.6, respectively. Isopropanol is generally more toxic than compounds with lower value. It has to be noted that the final IBE concentration of ATCC 824(pFC002) cultures (16 g/L) was still higher than that of NRRRL B593 cultures (13 g/L) suggesting that the solvent sensitivity is a strain-dependent characteristic.

Under all culture conditions tested, the overexpression of all genes encoding enzymes of the acetone route (ctfA, ctfB and adc), along with expression of adh gene, conferred to ATCC 824(pFC007) high solvent production rate and high final solvent titres. The use of thl promoter to control the expression of ctfA and ctfB genes initiated excretion of isopropanol before those of other solvents. Recently, Lee et al. (2012) have developed a transformant comparable with ATCC 824(pFC007) in which expression of isopropanol pathway genes were controlled by two adc promoters. In batch culture with pH regulation at 5.0, the maximal end-concentration of IBE was only 17.1 g/L of which 6.1 g/L was isopropanol. The difference in solvent productions observed in the two studies might result from the culture mode applied. Fed-batch with gas stripping was used and was found to improve IBE production by 35.6 g/L (Lee et al. 2012) but this type of process has never been scaled up.

The role of each gene involved in the pathway from acetoacetyl-CoA to acetone in the enhancement of ATCC 824(pFC007) fermentation performances was clarified by expressing two derivative plasmids. The

Cultures were performed in 1 L-working volume of CM1 containing 3.0 g/L ammonium acetate and 90 g/L glucose. All data are given as the mean of two or three fermentations the standard error to the mean is indicated in brackets.

* a negative value (−) indicates that initial acetic acid from culture medium was partially consumed.
overexpression of the \textit{ctfA} and \textit{ctfB} genes increased both the speed and the extent of acid assimilation while the overexpression of the \textit{adc} gene had a little effect (Table 3).

This result indicates that decarboxylation of acetocetate is not the real bottleneck. In a previous study on ABE production by ATCC 824, the overexpression of \textit{ctfA}, \textit{ctfB} and \textit{adc} genes controlled by the \textit{adc} promoter was studied at pH 5.5 (Mermelstein et al. 1993). As with our results, the combined overexpression of \textit{ctfA}, \textit{ctfB} and \textit{adc} increased the solvent production by transformants, whereas expression of \textit{adc} gene alone had little effect. Unlike our results, the combined expression of \textit{ctfA} and \textit{ctfB} genes without \textit{adc} was found to have a limited effect. Therefore, the impact of \textit{ctfA} and \textit{ctfB} overexpression observed in our study might have been supported by the chemically calalysed decarboxylation of acetocetate (Hay and Bond 1967).

\section*{Conclusion}

The expression of \textit{ctfA} and \textit{ctfB} genes along with the \textit{adh} gene in \textit{C. acetobutylicum} appears to be a promising way for constructing efficient isopropanol/ethanol producers. The transformants in the present study produce the highest total IBE concentration reported for clostridial batch cultures without online IBE removal (24.4 g/L). As the IBE alcohol mix is considered to be a valuable fuel additive, the transformants obtained represent a step forward towards the development of an industrial IBE process for the production of biofuels.
